# **Statistics**

Lecture 7
Inferential statistics

By Pr.Chelli

### Lecture objectives

Introducing inferential statistics / non parametric and parametric tests

## Introduction

Descriptive statistics make no inferences or predictions, they simply report what has been found. Inferential statistics, by contrast, make inferences and predictions based on the data gathered. This includes, for example, hypothesis testing, correlations, different testing...

Inferential statistics are often more valuable for researchers and typically they are more powerful. This lecture introduces you to this type of statistics which are based on the findings of descritptive statistics and helps you complete your research by testing the hypothese formulated in your research study.

## Inferential statistics

- □ Inferential statistics infer from the data whether the predicted effect of the independent variable actually occurred in the experience. We are making inferences from observable data to causal relationships between variables (Miller, 1985, p.41).
- □ Inferential statistics infer from the sample to the population.
- ☐ They determine probability characteristics of population based on the characteristics of the sample.
- □ They allow to generalize the findings to a larger group.

# Statistical significance

The main concern of inferential statistics has traditionally been the testing of 'statistical significance'.

Statistical significance denotes whether a particular result in a sample is true for the whole population. If the result is non-significant, this means that we cannot be certain that it did not occur by chance.

# Continued

Significance is measured by probability coefficient (p), which can range form 0 to + 1.

A p of 0.25 means that the obtained result might be due to pure chance in 25 percent of the cases.

In social sciences, significance is typically measured by **0.05**. This means that the result might be **due to pure chance in 5% of the cases.** 

## Statistical tests

Probability theory allows to produce **test statistics** using mathematical formulas.

A test statistic is a numerical value that is used to decide whether to accept or reject the null hypothesis.

A statistical test is simply a device for calculating the likelihood that our **results are due to chance fluctuation** between the groups. Different tests calculate this likelihood in different ways, depending on the design of the experiment and the nature of the dependent variable (Miller, 1984, p. 42).

# continued

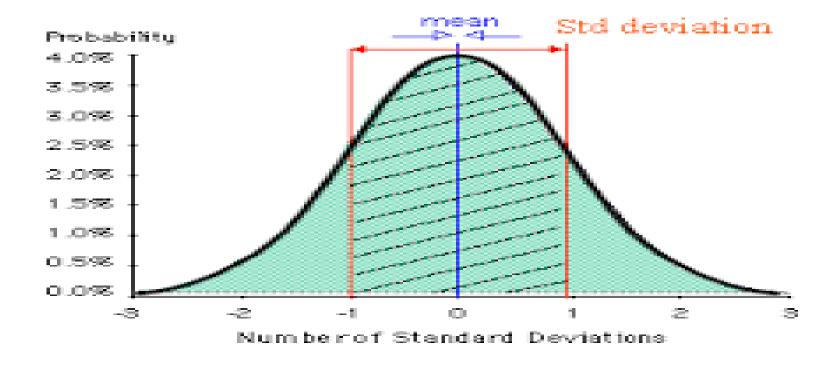

A statistical test is used to determine the probability that the observed results could have occurred under the null hypothesis. If this probability is **less than**, **or equal to 0.05**. **the null hypothesis is rejected** in favour of the alternate hypothesis and **the results are said to be significant**.

## Normal distribution

Normal distribution is the most important probability in statistics. It is an arrangement of a data set in which most values cluster around the central peak and the rest taper off symetrically toward either extreme.

## continued

A normal distribution has a bell shaped density curve by its mean and standard deviation. The density curve is symmetrical, centered about its mean, with its spread determined by its standard deviation.

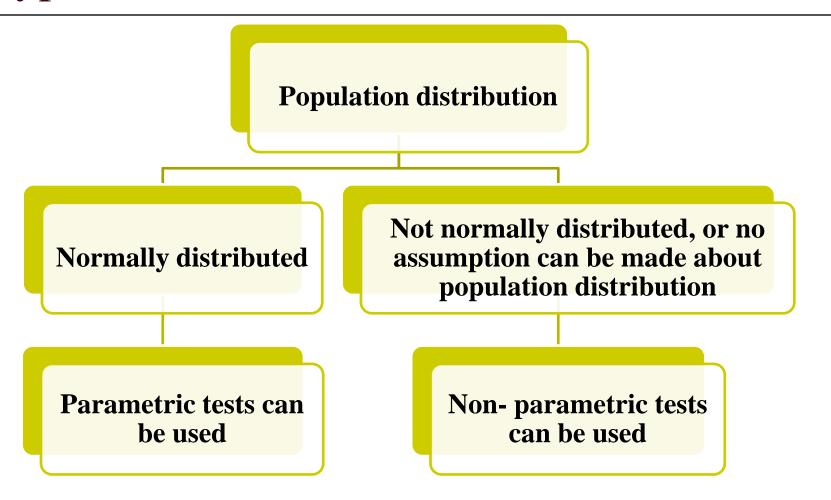

- □ The bell-shaped curve indicates that most values fall near the central value, with fewer from the centre and the rest fall symetrically.
- ☐ If the sample size is large, it is assumed that the distribution is normal.

# Testing hypotheses

To test a hypothesis, a **statistical test** is required.

- □ A statistical test is used to determine the probability that the observed results could have occurred under the null hypothesis.
- □ If this probability is less than, or equal to 0.05 the null hypothesis is rejected in favour of the alternate hypothesis, and the results are said to be significant.

# Types of statistical tests

# Parametric versus parametric tests

There are basically two types of statistical tests—parametric and non-parametric

#### **Use Parametric Test**

If data is Normally distributed

Sample Size *more* than 30

#### Use Nonparametric Test

If data is **not** distributed Normally Sample Size *less* than 30

# Difference between parametric and nonparametric tests

# Parametric tests Non parametric tests

- The measurement of variables is done on interval and ratio level.
- •The measue of central tendency is the mean.

- •The measurement of variables is done on nominal or ordinal level.
- •The measue of central tendency is the median.

## **Examples of Parametric and non-parametric tests**

|                                 | Parametric tests                                     | Non parametric tests                                  |
|---------------------------------|--|---|
| Assumed distribution            | Normal   | Any   |
| Typical data                    | Numerical  | Ordinal or nominal                                    |
| Usual central measure           | Mean   | Median , mode   |
| Advantages                      | Can draw more conclusions                            | Simplicity; less affected by outliers                 |
| Describe one group              | Mean , SD  | Median, interquartile range<br>Proportion             |
| Independent measures,2 groups   | Unpaired t test                                      | Chi-square test, Fisher's test<br>Mann-Whitney U test |
| Independent measures ,>2 groups | ANOVA  | Kruskal – Wallis test<br>Chi-square test              |
| Repeated measures,2 conditions  | Paired t test  | Wilcoxon sign rank, Mc Nemar's<br>Chi-square test     |
| Repeated measures,>2 conditions | ANOVA  | Friedman's test<br>Chi-square test                    |
| Regression                      | Simple linear regression or<br>Non-linear regression | Non parametric regression                             |

## How to choose a statistical test?

There are **two major factors** that determine the correct test for any particular set of experimental results: (1) **the research design** and (2) the **nature of the dependent variable**, that is, the actual data (Miller, 1984,p.53).

From the list of statistical tests seen in slide 15, the following will be presented:

- 1. The Man-whitneyU test and the chi-square test.
- 2. The paired and unpaired tests

# The Man-Whitney test

The Mann-Whitney makes no assumptions about the populations from

which the samples have been drawn (**non-parametric**), and can be used with **ordinal or interval scaling** (Miller, 1984,p.77).

#### **Example**

A typical application of the test might involve the comparison of two

independent groups of subjects who were taught to read by different methods and subsequently rated on a scale of reading 'fluency' from 1 to 10. (ibid.69).

# The Chi-square test

- The Chi-square statistic is a **non-parametric** (distribution free) tool designed to analyze group diff erences when the dependent variable is measured at a **nominal level**.
- The chi-square test is useful for the comparison of groups in which subjects' behaviour has been classified into **discrete**, **qualitatively different categories**. The observations are then *frequency counts* of the number of individuals coming within each category.
- □ The test may be used to determine whether two groups differ in terms of the proportion of individuals falling into one category rather than another ((Miller, 1984,p.77).
- □ An example of data suitable for chi-square is sex of person and choice of favourite leisure entertainment

## Paired t-test versus unpaired t-test

Both paired (dependent samples t-test) and unpaired (independent samples t-test) tests check if the difference between two means is significant.

□ The paired-samples t-test (equivalent to a one-sample-t-test) compares scores of the same group at two different times.

□ The unpaired t-test, called the independent samples t-test (a two-samples t-test) compares scores for two different groups.

# Examples of statistical tests

The most statistical tests include:

- □ Chi-square test: can be used for nominal (categorical) data to determine whether a relationship between categorical data is likely to reflect a real association between these two variables in the population.
- □ T-test: allows the comparison of the mean of two groups.
- □ ANOVA test: Analysis of variance : allows the comparison of three or more groups.

□ Linear regression: focuses on prediction. A single independent variable is used to predict the value of a dependent variable.

Does age predict income?

■ Mann Whitney test: is frequently used as an alternative to the t-test for independent samples. It can be used with data measured most of the time on an ordinal scale.

# Types of analyses

**Univariate analysis**: the analysis of one variable: mean, median, mode and standard deviation.

Eg. How many students have the average?

**Bivariate analysis:** is a kind of data that explores the association between two variables

- □ Pearson's correlation test
- □ T-test
- □ Spearrman Rho correlation test
- □ Mann- Whitney test
- □ Linear regression test

Multivariate: the analysis of more than two variables.

### Some examples:

☐ Multi-regression (multiple linear regression): is a statistical technique that uses several explanatory variables (independent variable) to predict the outcome of a response variable (dependent variable).

# Test yourself

- 1. How do we know that a population is normally distributed?
- 2. what are the factors to be taken into consideration in choosing a statistical test?
- 3. What is the statistical test that you are supposed to use in your research?
- 4. When isn't a statistical test required?
- 5. Which statistical test can you use in likert scale?
